Create Executable Python Script

The best way, which is cross-platform, is to create `setup.py`, define an entry point in it and install with pip.

Say you have the following contents of `myscript.py`:

```
def run():
    print('Hello world')
```

Then you add `setup.py` with the following:

```
from setuptools import setup
setup(
    name='myscript',
    version='0.0.1',
    entry_points={
        'console_scripts': [
            'myscript=myscript:run'
        ]
    }
)
```

Entry point format is `terminal_command_name=python_script_name:main_method_name`

Both files should be placed into the same directory

Finally install with the following command.

```
pip install -e /path/to/script/folder
```

-e stands for editable, meaning you'll be able to work on the script and invoke the latest version without need to reinstall

After that you can run `myscript` from any directory.
